A call to action and a lifecourse strategy to address the global burden of raised blood pressure on current and future generations: the Lancet Commission on hypertension

Michael H. Olsen*, Sonia Y. Angell, Samira Asma, Pierre Badier, Dylan Burger, Julia A. Chikina, Alberto Damasceno, Christian Delle, Anne-Paule Ginerat-Riquelme, Dagnmar Hering, Patricia Lopez-Jaramilla, Fernando Martinez, Vlado Pavlovic, Ernst R. Ritzschel, Giuseppe Schillaci, Almeta E. Schutte, Angelo Scionti, James E. Shearman, Kristian Woodford, Ji-Guang Wang

Executive summary

Elevated blood pressure is the strongest modifiable risk factor for cardiovascular disease worldwide. Despite extensive knowledge about ways to prevent as well as to treat hypertension, the global incidence and prevalence of hypertension and, more importantly, its cardiovascular complications are not reduced—partly because of inadequacies in prevention, diagnosis, and control of the disorder in an ageing world.

Life expectancy by county, race, and ethnicity in the USA, 2000-19: a systematic analysis of health disparities

Summary
 Background There are large and persistent disparities in life expectancy among racial-ethnic groups in the USA, but most research has been primarily descriptive. This study estimated life expectancy for five racial-ethnic groups in 100 US counties over 20 years, to describe spatial-temporal variations in life expectancy and disparities between racial-ethnic groups.

Methods We applied novel machine-learning methods to death registration data from the US National Vital Statistics System and population data from the US National Center for Health Statistics to estimate annual age-specific and age-specific mortality rates stratified by county and racial-ethnic group (American Indian or Alaska Native [AIAN], non-Latino and non-Hispanic Black [non-Latino and non-Hispanic Black], non-Latino and non-Hispanic American Indian or Alaska Native [non-Latino and non-Hispanic AIAN], non-Latino and non-Hispanic Asian or Pacific Islander [non-Latino and non-Hispanic Asian], and non-Latino and non-Hispanic Latino or Hispanic [non-Latino and non-Hispanic Latino or Hispanic]) from 2000 to 2019. We applied these mortality rates to competing risks and disability-free death coefficients and then constructed age-adjusted life expectancy estimates.

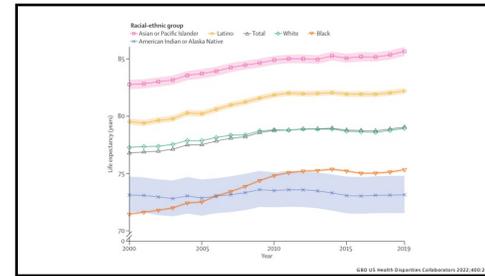

Findings Between 2000 and 2019, trends in life expectancy differed among racial-ethnic groups and across counties. Nationally, there was an increase in life expectancy for people who were Black (change: 3.9 years [95% confidence interval (CI) 3.6 to 4.2], Latinx (2.7 years [CI 2.4 to 3.0]), non-Latino and non-Hispanic AIAN (2.1 years [CI 1.7 to 2.5]), non-Latino and non-Hispanic Asian or Pacific Islander (1.9 years [CI 1.6 to 2.2]), and White (1.7 years [CI 1.5 to 1.9]) over the period. The largest difference in life expectancy in the Black population compared with the White population decreased during the period, whereas the largest difference for the AIAN population compared with the White population increased. In both cases, these patterns were mitigated across counties. The largest difference in life expectancy for the AIAN and Latino populations compared with the White population increased at the national level from 2000 to 2019, because the difference declined in a similar number of counties (201 and 242 counties, respectively). For the Latino population and in some counties (101 [30%] of the counties for the AIAN population, 101 of all racial-ethnic groups, approximately in life expectancy were more unequal across counties and larger from 2000 to 2019 than from 2000 to 2002.

Interpretation Disparities in life expectancy among racial-ethnic groups are widespread and enduring. Localized data are crucial to address the root causes of poor health and early death among disadvantaged groups in the USA, determine health disparities, and increase longevity for all.

The Population Health Outcomes and Information Exchange (PHOENIX) Program - A Transformative Approach to Reduce the Burden of Chronic Disease

The Population Health Outcomes and Information Exchange (PHOENIX) Program - A Transformative Approach to Reduce the Burden of Chronic Disease

ABSTRACT

This review article introduces a transformative vision to reduce the population burden of chronic disease by focusing on data integration, analytics, implementation and community engagement, known as PHOENIX (The Population Health Outcomes and Information Exchange). The approach leverages a state level health information exchange and multiple other resources to facilitate the integration of clinical and social determinants of health data with a goal of achieving more population health monitoring and management. After receiving historical context, we describe how multiple data modalities can be used to facilitate core public health services, before discussing the convenors and challenges that lie ahead.

Keywords: Health information exchange; data integration; epidemiology; electronic health record; translational science; social determinants of health.

Circulation: Cardiovascular Quality and Outcomes

CARDIOVASCULAR PERSPECTIVE

Cardiometabolic Risk Factor Control During Times of Crises and Beyond

The world is currently suffering through one of the greatest crises of the last century. The coronavirus disease 2019 (COVID-19) pandemic is taking an enormous toll on public health and straining medical resources in an unprecedented fashion. Our attention on efforts focused on meeting the immediate threat. Nevertheless, we wish to call attention that during major catastrophes the health consequences of chronic disease, in particular cardiometabolic risk factors (CMRFs), continue to be exacerbated. In fact, new and serious problems also participate with the catastrophic and complex to hamper our already imperfect ability to control CMRFs. Our objective is to raise awareness that we need to anticipate and not just be reactive to the possible opening of a second crisis we term disastrous CMRFs. This refers to the worsening of CMRFs and their control rates during and following a major disaster. Health care providers, in particular cardiologists, need to recognize the potential for this serious problem as it could portend a resurgence of cardiovascular morbidity and mortality if not addressed. The COVID-19 pandemic should also serve as a wake-up call to the unprepared. In our healthcare model that culture to undermine the successful management of CMRFs is spread. This current crisis can be a catalyst for approaching practices and retooling critical care capacities that will be beneficial moving forward and serve as a blueprint against future crises.

RESEARCH LETTER

Utilizing Mobile Health Units for Mass Hypertension Screening in Socially Vulnerable Communities Across Detroit

Robert D. Brook, Kateri Dandari, Brittany Foster, Reed M. Frost, Catherine Gaughan, Paul Karlan, Brian Reed, Arlene L. Green, Stephen Kherif, Wang G. Liang

Nearly half of all adults in the United States have hypertension, defined as a blood pressure (BP) reading of 130/80 mmHg or higher. While the prevalence (50%) and control rates (18%) are worse in Black patients, hypertension-related consequences of health in socially vulnerable populations further exacerbate these disparities while reducing hypertension awareness and access to health care. These places exemplify the crisis like the city of Detroit (DE), Black small dense housing (SDH) neighborhoods, and the presence of the Detroit River. The DE SDH neighborhoods are characterized by high rates of hypertension, diabetes, and obesity. As such, the public health consequences of high rates of hypertension and related conditions are significant. The SDH neighborhoods are characterized by high rates of hypertension, diabetes, and obesity. As such, the public health consequences of high rates of hypertension and related conditions are significant.

\$20M awarded for scientific research to ensure health equity in preventing hypertension

Teams from Beth Israel Deaconess Medical Center, Johns Hopkins University School of Nursing, NYU Grossman School of Medicine, University of Alabama at Birmingham and Wayne State University receive American Heart Association research grants to study high blood pressure prevention in underserved populations.
